

## CLAIMS

1           1.     Method for verifying a transformer of a so-called source code into a  
2     so-called transformed code designed for an embedded system, said source and  
3     transformed codes being associated with virtual machines, characterized in that it  
4     comprises at least the following steps:

5           - determining, for each of said source (1) and transformed (3) codes, a first  
6     common subset (13), constituting a single virtual machine that factors in the behavior  
7     of these two codes (1,3);

8           - determining, for each of said source (1) and transformed (3) codes, a second  
9     subset (10, 30) constituted by a plurality of so-called auxiliary functions ( $10_i - 30_i$ )  
10    used by said single virtual machine, said auxiliary functions ( $10_i - 30_i$ ) representing  
11    residual differences between said source (1) and transformed (3) codes;

12          - associating said auxiliary functions in pairs, a first auxiliary function ( $10_i$ ) of  
13    each pair belonging to said second subset (10) associated with said source code (1)  
14    and a second auxiliary function ( $30_i$ ) of each pair belonging to said second subset (30)  
15    associated with said transformed code (3);

16          - verifying (6) a given correspondence property between said auxiliary  
17    functions ( $10_i - 30_i$ ) of all of said pairs; and

18          - verifying that said transformation of the source code (1) into a transformed  
19    code (3) by said converter (2) satisfies said given correspondence property.

1           2.     Method according to claim 1, characterized in that said correspondence  
2     property is a logical relation, so that said auxiliary functions of each of said pairs ( $10_i$   
3     -  $30_i$ ), when executed, generate results linked by said logical relation, and in that this  
4     relation is the identity relation for so-called observable entities of each of said source  
5     and transformed codes, for any pair of auxiliary functions, so that the functionalities  
6     of said source code (1) are retained when said transformation into said transformed  
7     code (3), and said verification of the code transformer (2), are performed.

1           3.     Application of the verification method according to either of claims 1  
2     and 2 to a code transformer (2) that generates, from said source code (1), a  
3     transformed code (3) designed to be stored in memory means (71) of a chip card (7).

1           4.       Application according to claim 3, characterized in that, said  
2 transformed code being a program written in the virtual machine of a given computer  
3 language, said chip card (7) is a chip card that stores a plurality of software  
4 applications ( $A_1$  through  $A_n$ ) written in this transformed code (3).

1           5.       Application according to claim 3 or 4, characterized in that said source  
2 code (1) is a program written in the "JAVA" (registered trademark) virtual machine  
3 and said transformed code (3) is a program written in the "JAVA CARD" (registered  
4 trademark) virtual machine.
